#### Introduction

This document contains the statistical analysis performed in the publication *Pathobiochemical signatures of cholestatic liver disease in bile duct liquted mice*.

A comprehensive data set of serum markers, histological parameters and transcript profiles was compiled at 8 time points after bile duct ligation (BDL) in mice, comprising different stages of the disease. The data set consists of  $N_r = 5$  repeats ( $N_r = 3$  for the measured antibodies) for  $N_t = 8$  time points denoted by  $t_1, ..., t_{N_t}$  consisting of a total  $N_f = 154$  measured parameters in the following referred to as factors (Fluidigm gene expression, antibodies, serum markers, histological measurements).

The main steps of the analysis comprise

- Explorative data anaysis
- Dimension reduction via ANOVA
- Correlation analysis based on time course correlation measure
- Hierarchical clustering
- Decision trees for prediction

The complete data set, source code and documentation of this analysis is available from <a href="https://github.com/matthiaskoenig/bdl-analysis">https://github.com/matthiaskoenig/bdl-analysis</a> .

The following naming conventions are used

- factor : one of the measured quantities/parameters over time, i.e. either
  - gene expression of a single gene (e.g. Actb);
  - one of the biomarkers (e.g. ALT, albumin, bilirubin)
  - one of the histological markers (e.g. BrdU-positive Kupffer cells)
  - one of the antibodies (e.g. CTGF, S100A4)
- time point: a single value  $t_i$  from the measured time points 0h (control), 6h, 12h, 18h, 30h, 2d, 5d, 14d
- sample: one of the  $N_t \cdot N_r = 40$  mice, i.e. a one of the repeats for a given time point

The results of the analysis are written to the results directory defined via the BDL\_RESULTS environment variable. To reproduce this analysis create the respective variable.

```
# read the folder for results from environment variable
resultsPath <- Sys.getenv("BDL_RESULTS")
if (identical(resultsPath, "")){
   stop("No results folder defined, set the BDL_RESULTS environment variable")
} else {
   print(resultsPath)
}</pre>
```

## [1] "/home/mkoenig/git/bdl-analysis/results"

```
# create data subfolder to store analysis results
dir.create(file.path(resultsPath, 'data'), showWarnings=FALSE)
```

#### Explorative data analysis

#### Data import

In a first step the processed data set is loaded from the data folder. The data consists of the time course data for all factors (BDLdata), additional information for the factors (BDLfactors), the sample definition, i.e. the assignment of sample ids to respective time point and repeat (BDLsamples), and a mapping of the Fluidigm (gene) probe ids to UniProt identifiers (BDLprobes).

```
suppressPackageStartupMessages(library(BDLanalysis))
suppressPackageStartupMessages(library(calibrate))
suppressPackageStartupMessages(library(pander))
dir.create(file.path(resultsPath, 'control'), showWarnings=FALSE)
# path definition
baseLoc <- system.file(package="BDLanalysis")</pre>
extPath <- file.path(baseLoc, "extdata")</pre>
# load data
data(BDLdata)
data(BDLsamples)
data(BDLfactors)
data(BDLprobes)
# counters
Nr <- 5 # repeats
Nt <- length(levels(BDLsamples$time_fac)) # time points</pre>
# store all data sets in the results folder
save(BDLdata, file=file.path(resultsPath, "data", "BDLdata.Rdata"))
save(BDLsamples, file=file.path(resultsPath, "data", "BDLsamples.Rdata"))
save(BDLfactors, file=file.path(resultsPath, "data", "BDLfactors.Rdata"))
save(BDLprobes, file=file.path(resultsPath, "data", "BDLprobes.Rdata"))
```

In addition to the individual data points per time point, the mean data averaged over the  $N_r$  repeats per time points is used in parts of the correlation analysis. This mean factor data set is calculated once at the beginning via

```
BDLmean <- bdl_mean_data(BDLdata, BDLsamples)
BDLmean.time <- as.numeric(levels(as.factor(BDLsamples$time)))</pre>
```

In total 154 factors were measured in the this BDL study falling in the categories: Antibodies, Biochemistry, GE\_ADME, GE\_Cytokines, GE\_Fibrosis, Histology. The majority of factors belongs herby to the 3 fluidigm chips with 47 probes per chip.

An overview of the number of factors per category is provided in the following table

```
cat_table <- as.data.frame(table(BDLfactors$ftype))
colnames(cat_table) <- c("Category", "Freq")
set.caption(sub(".", " ", "Factors per category", fixed = TRUE))
pander(cat_table)</pre>
```

Table 1: Factors per category

Category	Freq
Antibodies	3

Category	Freq
Biochemistry	4
$GE\_ADME$	47
$GE\_Cytokines$	47
$GE\_Fibrosis$	47
Histology	6

```
rm(cat_table)
```

#### Data visualization

#### Time course of single factors

In a first step overview plots of the raw and mean data for all individual factors are generated. These are available in the resultsPath/factors folder

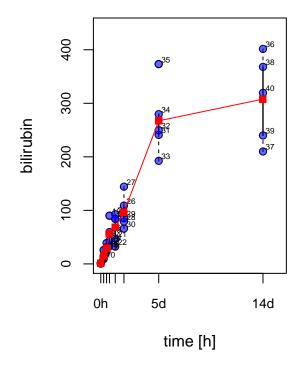

```
# Create figures for all factors
factors_path <- file.path(resultsPath, 'factors')
dir.create(factors_path, showWarnings=FALSE)
plot_all_factors(path=factors_path)
rm(factors_path)</pre>
```

The example for a single factor is depicted below, here for the factor bilirubin.

```
plot_single_factor('bilirubin', path=NULL)
```

## bilirubin (Biochemistry)

## bilirubin (Biochemistry)

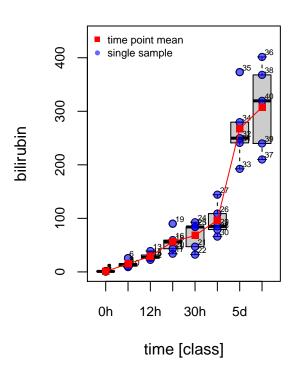

Figure Single factor: Plot of the raw time course data for a single factor, here for bilirubin. On the left the data is plotted against the time [h], on the right against the different time classes. Individual data points are depecticed in blue with the respective sample number shown next to the data points. The mean averaged of the repeats per time point are depicted in red. Box-and-whisker plots were added with default R parameters of boxwex=0.8, staplewex=0.5, outwex=0.5.

#### Time course of all factors (Heatmap)

In a next step the heatmap of the full data set was generated, i.e. of all time points and repeats. This provides a first overview over the complete data set. Rows correspond to the individual factors (factor order corresponding to the original data set: GE\_ADME, GE\_Cytokines, GE\_Fibrosis, Biochemistry, Histology, Antibodies). Columns correspond to the 40 samples with 5 subsequent samples belonging to one of the 8 time points (with from left to right: 0h, 6h, 12h, 18h, 30h, 2d, 5d, 14d). The data is row scaled, i.e. every individual factor is scaled to have mean zero and standard deviation one.

```
suppressPackageStartupMessages(library(gplots))
suppressPackageStartupMessages(library("RColorBrewer"))
# define horizontal and vertical helper lines
v_{lines} <- ((1:Nt)*Nr+0.5)
factor_types <- c("Antibodies", "Histology", "Biochemistry", "GE_Fibrosis", "GE_Cytokines", "GE_ADME")
factor_table <- table(BDLfactors$ftype)</pre>
h_lines <- 0.5 + cumsum(factor_table[factor_types])</pre>
timecourse_heatmap <- function(){</pre>
  # create better row names
  dtmp <- BDLdata
  rownames(dtmp) <- paste(rownames(BDLsamples), BDLsamples$time_fac, sep=" ")
  # heatmap colors
  hmap_colors <- HeatmapColors()</pre>
  # colors for factor groups
  colorset <- brewer.pal(length(factor_types), "Set2")</pre>
  color.map <- function(factor_id) {return(colorset[ which(factor_types==BDLfactors$ftype[which(BDLfact</pre>
  factorColors <- unlist(lapply(BDLfactors$id, color.map))</pre>
  # heatmap
  heatmap.2(t(as.matrix(dtmp)), col=hmap_colors(100), scale="row", dendrogram="none", Rowv=NULL, Colv=N
            key=TRUE, trace="none", cexRow=0.5, keysize=0.8, density.info="none",
            RowSideColors=factorColors,
            add.expr=abline(v=v_lines, h=h_lines, col="black", lwd=0.5),
            main="Heatmap of BDL time course data")
            # xlab="sample", ylab="factor")
  # legend
  legend("left",
      inset=c(-0.03,0),
      legend = rev(factor_types), # category labels
      col = rev(colorset), # color key
      lty= 1, lwd = 10, cex = 0.7, bty="n"
  )
}
# plot to file
pdf(file.path(resultsPath, "control", "timecourse_heatmap.pdf"), width=10, height=10, pointsize=12)
timecourse_heatmap()
invisible(dev.off())
```

```
timecourse_heatmap()
```

```
# cleanup
rm(factor_table, h_lines, v_lines)
```

Figure All factors: Heatmap of the complete data set, i.e. all factors and repeats over time. The data is row scaled, i.e. every individual factor is scaled to have mean zero and standard deviation one, with positive Z-score in blue, negative Z-score in red. The row order is according to the factor categories, the order within the fluidigm chips according to the order of the probes on the chip. the respective categories are depicted on the left.

**Results**: Various patterns are visible in the plotted raw data:

- Two main classes of response can be observed. One class with an increase in the early phase up to 6h after BDL (many of the ADME genes fall into this class) and a second class increasing in the later stage after 2-5 days after BDL. Many of the genes on the Cytokines and Fibrosis chips as well as some of the biochemical, histological and antibody fall in this second class.
- The individual animals show heterogeneous responses to BDL. Within one time point the 5 repeats can show very different patterns. For instance at time 6h after BDL 3/5 of the mice show a marked increase in the ADME genes, whereas 2/5 do not show such a marked increase. Another example is the mice sample 27 at time 2d, with a high increase in the genes on the Fibrosis chip, which is not observed in the other 4 samples at time 2d.

#### Actb quality control

Actb (Actin, cytoplasmic 1) probes were included on all Fluidigm chips (GE\_ADME, GE\_Cytokines, GE\_Fibrosis) and not used in the normalization of the gene expression data. Hence, ActB can serve as quality control for the technical reproducibility of the Fluidigm chips. If the data is reproducible between chips the pairwise correlation between all individual Actb measurements should have high correlation coefficients close to 1. Plotting the data of the Actb measurements of two chips against each other should lie on a straight line

```
# Actb control figure
plot_actb_control <- function(){</pre>
  par(mfrow=c(2,3))
  plot_single("Actb")
  plot_single("Actb.x")
  plot_single("Actb.y")
  plot_cor_pair("Actb", "Actb.x", single_plots=FALSE)
  plot_cor_pair("Actb", "Actb.y", single_plots=FALSE)
  plot_cor_pair("Actb.x", "Actb.y", single_plots=FALSE)
  par(mfrow=c(1,1))
}
# plot to file
pdf(file.path(resultsPath, "control", "Actb_control.pdf"), width=10, height=6, pointsize=12)
plot_actb_control()
invisible(dev.off())
# calculate Spearman and Pearson correlation coefficients on N=8*5=40 data points
actb.spearman <- cor(data.frame(Actb=BDLdata$Actb,</pre>
```

#### Heatmap of BDL time course data

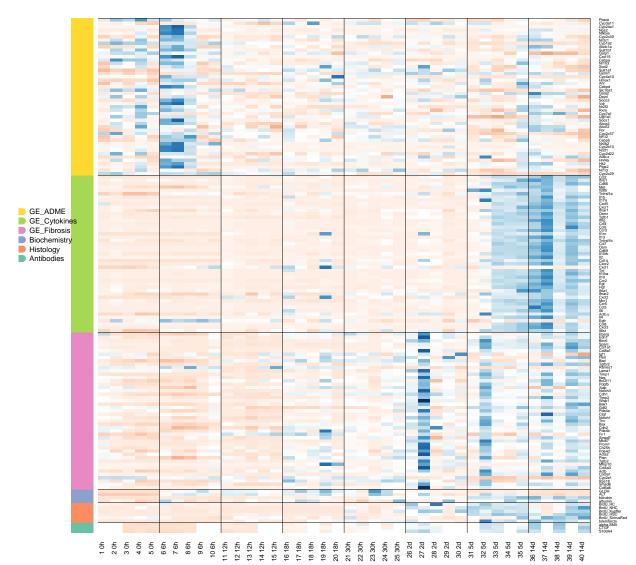

Figure 1:

Table 2: Spearman correlation of Actb controls

	Actb	Actb.x	Actb.y
Actb	1	0.908	0.944
Actb.x	0.908	1	0.917
$\mathbf{Actb.y}$	0.944	0.917	1

```
set.caption(sub(".", " ", "Pearson correlation of Actb controls", fixed = TRUE))
pander(round(actb.pearson, digits=3))
```

Table 3: Pearson correlation of Actb controls

	Actb	Actb.x	Actb.y
Actb	1	0.945	0.938
Actb.x	0.945	1	0.935
Actb.y	0.938	0.935	1

```
plot_actb_control()
```

```
rm(actb.pearson, actb.spearman)
```

Figure Actb Control: Correlation plot of the Actb probes from the 3 Fluidigm chips: Actb (fibrosis), Actb.x (ADME), Actb.y (Cytokines). The top row shows the individual time courses, the bottom row the pair wise plot of individual data points.

**Results**: The Actb Fluidigm gene expression measurements are highly reproducible for the measured chips, with Spearman as well as Pearson correlation coefficients all > 0.9 for pairwise Actb comparison.

#### Dimension reduction via ANOVA

#### ANOVA for single factor

A one-way analysis of variance (ANOVA) was applied to reduce the factors to the subset showing significant  $(p_{adjusted} < 0.05)$  changes during the time course. In its simplest form, ANOVA provides a statistical test of whether or not the means of several groups are equal, and therefore generalizes the t-test to more than two groups, with the groups being the sampled time points. The Holm's procedure was used to correct the p-values for any artificial p-value inflation due to multiple testing.

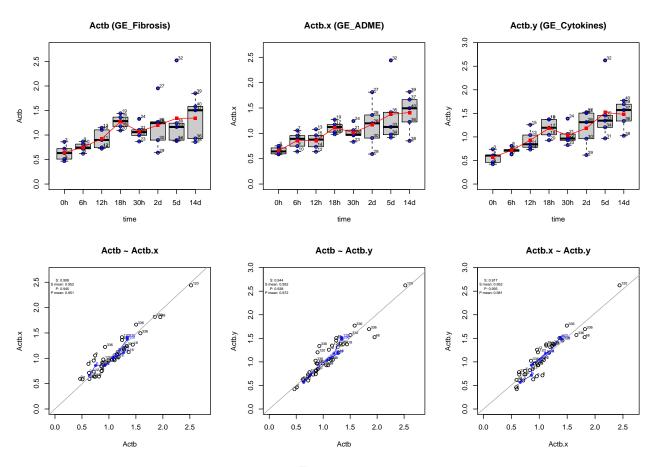

Figure 2:

For every of the individual factors in the BDL data set an ANOVA was calculated. Dimension reduction of the BDL data set was than performed by filtering out factors which did not significantly changing over time.

The BDLdata data set is reshaped into matrix format for the ANOVA calculation, with time points in rows and repeats as columns for every factor.

```
BDLmatrices <- bdl_matrix_data(BDLdata, BDLsamples)</pre>
```

The following shows the ANOVA calculation for a single factor, here for bilirubin.

```
# example ANOVA for one factor
  mat.anova <- t(BDLmatrices[['bilirubin']])</pre>
  colnames(mat.anova) <- levels(BDLsamples$time_fac)</pre>
  \# concatenate the data rows of df1 into a single vector r .
  r = c(t(as.matrix(mat.anova))) # response data
  # assign new variables for the treatment levels and number of observations.
  f = levels(BDLsamples$time_fac) # treatment levels
  k = 8
                                  # number of treatment levels
  n = 5
                                  # observations per treatment
  # create a vector of treatment factors that corresponds to each element of r in step 3 with the gl fu
  tm <- gl(k, 1, n*k, factor(f)) # matching treatments</pre>
  # apply the function aov to a formula that describes the response r by the treatment factor tm.
  # fit an analysis of variance model
  av \leftarrow aov(r \sim tm)
  # print out the ANOVA table with the summary function.
  summary(av)

#### ANOVA for all factors

Analog to the single factor ANOVA, the ANOVA is performed on all the factors. Hereby, a multitude of tests are performed, namely an ANOVA for every single factor. Consequently, the reported p-values of the ANOVA have to be adjusted via multiple testing procedures. Using the p-adjust function which given a set of p-values, returns p-values adjusted using one of several methods. The Bonferroni, Holm, Hochberg, Hommel are designed to give strong control of the family-wise error rate. We used the Holm's method for adjustment (Holm, S. (1979). A simple sequentially rejective multiple test procedure. Scandinavian Journal of Statistics 6, 65-70.).

```
# Calculation of ANOVA for all factors
df.anova <- all_factor_anova()
df.anova$sig <- sapply(df.anova$p.value, significant_code) # add significant codes

df.anova$p.holm <- p.adjust(df.anova$p.value, method ="holm", n = length(df.anova$p.value))
df.anova$sig.holm <- sapply(df.anova$p.holm, significant_code)
df.anova$ftype <- BDLfactors$ftype

# order factors by adjusted p-values
df.anova.ordered <- df.anova[with(df.anova, order(p.holm)),]
df.anova.ordered</pre>

The factors are filtered based on the respective acceptance level, with the cutoff for the adjusted p-value being  $p_{accept}$ , i.e. all factors with a ANOVA with  $p_{adjusted} \geq p_{accept}$  are filtered out. The filtered raw data is available as BDLdata.fil, the filtered mean data set as BDLmean.fil. All subsequent analyses are performed on the filtered data set, which is depicted in the following heatmap

save(df.anova, file=file.path(resultsPath, "data", "BDLanova.Rdata"))

```
p.accept = 0.05  # acceptance level
anova.accept = (df.anova$p.holm < p.accept)  # accepted subset
# subset of filtered data
BDLdata.fil <- BDLdata[, anova.accept]
BDLmean.fil <- BDLdata[, anova.accept]

# accepted
table(anova.accept)  # 64 rejected / 90 accepted (adjusted)

## anova.accept
## FALSE TRUE
## 64 90

# which factors were accepted in the various categories
fil_tab <- data.frame(
   table(BDLfactors$ftype[anova.accept]),
   table(BDLfactors$ftype),
   round(table(BDLfactors$ftype[anova.accept])/table(BDLfactors$ftype), 2)
)</pre>
```

```
fil_tab <- fil_tab[, c('Var1', 'Freq', 'Freq.1', 'Freq.2')]</pre>

Figure Timcourse Filtered: Plot of ANOVA filtered data set.

### Correlation analysis

For the correlation analysis between factors and the subsequent cluster analysis a correlation measure for time series data {Son2008} in combination with Complete-Linkage hierarchical clustering was used. This combination of methods provided the best enrichments on gene-expression time-series in a recent comparisons of methods {Jaskowiak2014, Jaskowiak2013} testing various correlation measures and clustering algorithms.

The calculation of correlation coefficients between factors i and j  $(i, j = 1, ..., N_p)$  was performed using the slightly modified correlation coefficient based similarity measure developed for clustering of time-course data  $(Y_{i,j}^{S2} \text{ and } Y_{i,j}^{R2})$  {Son2008}.  $Y_{i,j}^{S2}$  and  $Y_{i,j}^{R2}$  are linear combinations of (i) a classical correlation part based on Spearman correlation  $S_{i,j}^*$  in case of  $Y_{i,j}^{S2}$  or Pearson  $R_{i,j}^*$  in case of  $Y_{i,j}^{R2}$ , (ii) a component  $A_{i,j}^*$  accounting for the similarity in changes between two time courses, (iii) a component  $M_{i,j}^*$  comparing the location of minimum and maximum values of the time course (see {Son2008} for definitions)

$$Y_{i,j}^{S2} = w_1 S_{i,j}^* + w_2 A_{i,j}^* + w_3 M_{i,j}^*$$
  
$$Y_{i,j}^{R2} = w_1 R_{i,j}^* + w_2 A_{i,j}^* + w_3 M_{i,j}^*$$

 $R_{i,j}^*$  and  $S_{i,j}^*$  are hereby calculated on the individual data points for the factors i and j,  $A_{i,j}^*$  and  $M_{i,j}^*$  on the mean time courses averaged over the  $N_r$  repeated measurements. Throughout the analysis the following weights were used  $w_1 = 0.5$ ,  $w_2 = 0.3$ ,  $w_3 = 0.2$ .

In the calculation of the change component we used a Spearman correlation based measure  $(A^{**})$  instead of the originally proposed Pearson measure  $(A^*)$  resulting in the correlation scores  $Y_{i,j}^{S3}$  and  $Y_{i,j}^{S3}$ 

$$Y_{i,j}^{S3} = w_1 S_{i,j}^* + w_2 A_{i,j}^{**} + w_3 M_{i,j}^*$$

$$Y_{i,j}^{R3} = w_1 R_{i,j}^* + w_2 A_{i,j}^{**} + w_3 M_{i,j}^*$$

Herein,  $A_{i,j}^{**}$  calculates the correlation of changes between factors i and j based on Spearman correlation analog  $A_{i,j}^{*}$  as

$$A_{i,j}^{**} = (S(d_i, d_j) + 1)/2$$

$$A_{i,j}^* = (R(d_i, d_j) + 1)/2$$

The reason for this adaption was that initial analysis showed a strong dependency of the change components on outliers.

## Color Key -4 0 2 4

#### **ANOVA Filtered BDL factors**

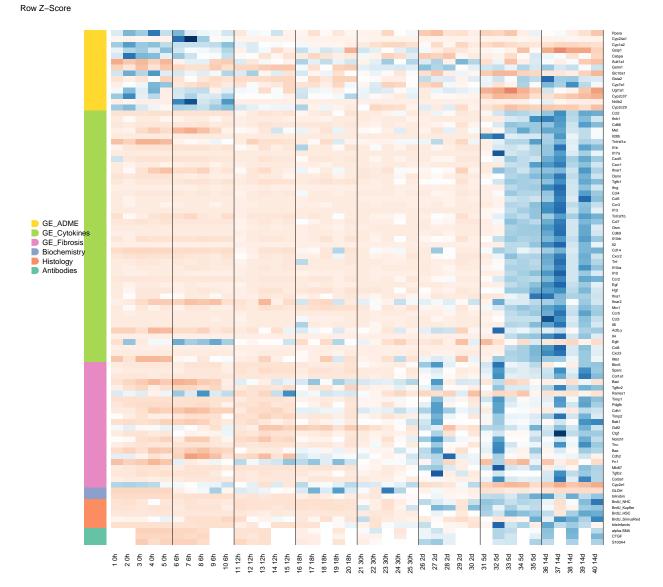

Figure 3:

All calculated correlation scores  $Y^S$  and  $Y^R$  are transformed from [0, 1] to [-1, 1] via

$$Y_{norm}^S = 2(Y^S - 0.5)$$

$$Y_{norm}^{R} = 2(Y^{R} - 0.5)$$

In addition to the used  $Y^S$  and  $Y^R$  correlation scores Pearson (R) and Spearman (S) correlations were calculated for comparison.

```
suppressPackageStartupMessages(library(corrplot))
dir.create(file.path(resultsPath, 'correlation'), showWarnings=FALSE)

# list of calculated correlation methods
correlation_methods <- c("pearson", "spearman", "ys1", "ys2", "ys3", "yr1", "yr2", "yr3")

# The calculated correlation matrices are stored in the `cor.matrices
# Provides simple access to the respective correlation matrix.
cor.matrices <- vector("list", length=length(correlation_methods))
names(cor.matrices) <- correlation_methods</pre>
```

#### Pearson & Spearman correlation

In a first step Pearson  $R_{i,j}$  and Spearman  $S_{i,j}$  correlation were calculated for the subset of filtered factors.

```
# Spearman and Pearson on individual data points
cor.matrices$pearson <- cor(BDLdata.fil, method="pearson", use="pairwise.complete.obs")
cor.matrices$spearman <- cor(BDLdata.fil, method="spearman", use="pairwise.complete.obs")</pre>
```

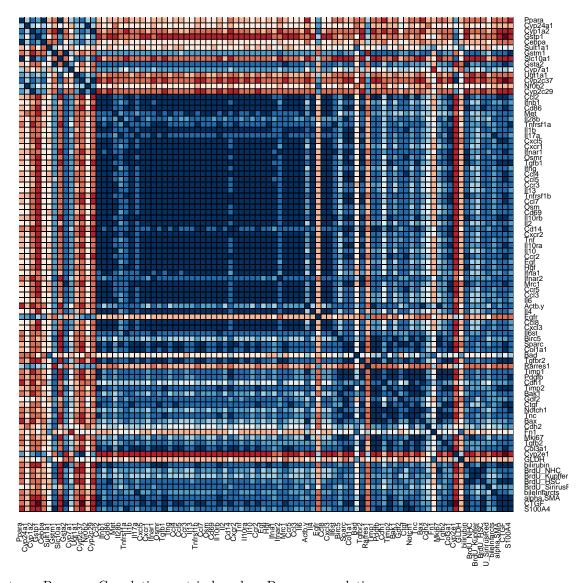

Heatmap plot of the correlation matrices with factors in original order

```
# Heatmap of correlation matrix
correlation_heatmap <- function(method){</pre>
  data <- cor.matrices[[method]]</pre>
  if(is.null(data)){
    stop("Correlation matrix does not exist for method: ", method)
  cor_colors <- HeatmapColors() # color palette for correlation (red - white - blue)
  heatmap.2(data, col=cor_colors(10), scale="none",
          key=TRUE, symkey=FALSE, trace="none", cexRow=0.8, cexCol=0.8,
          main=method,
          density.info="none", dendrogram="none",
          Rowv=NULL, Colv=NULL,
          keysize=0.8, key.xlab = method,
          #revC=TRUE,
          sepwidth=c(0.01,0.01),
          sepcolor="black",
          colsep=1:ncol(data),
          rowsep=1:nrow(data))
}
```

```
# Pearson correlation (no clustering)
correlation_heatmap(method="pearson")
```

#### pearson

 $\label{eq:Figure Heatmap Pearson: Correlation matrix based on Pearson correlation.$ 

```
# Spearman correlation (no clustering)
correlation_heatmap(method="spearman")
```

#### spearman

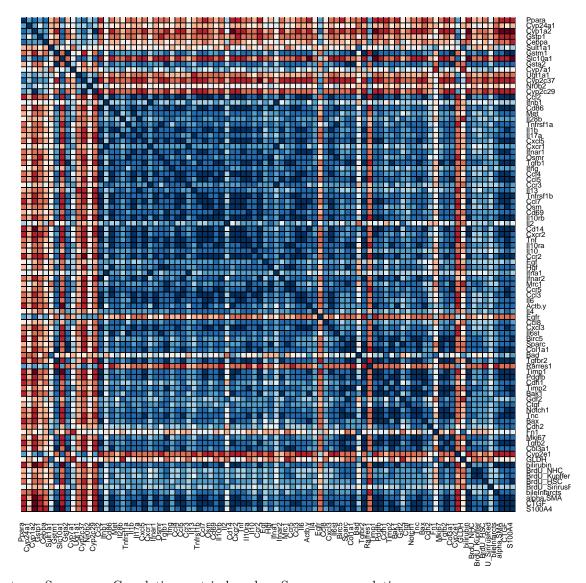

Figure Heatmap Spearman: Correlation matrix based on Spearman correlation.

The pearson correlation is highly sensitive to outliers (correlation between factors, but also in the changes between time points). Prelimary analysis of  $A^*$  showed similar problems, so we used  $A^{**}$  in  $Y^{S3}$  instead.

#### YS & YR correlation

Here, the time-course based correlation measurements  $Y^{S1}$ ,  $Y^{S2}$ ,  $Y^{S3}$ ,  $Y^{R1}$ ,  $Y^{R2}$  and  $Y^{R3}$  are calculated for the factors in the filtered BDL data set. To create the correlation matrix all pairwise correlations between all factors are calculated.

```
# weighting factors
w \leftarrow list(w1=0.5, w2=0.3, w3=0.2)
# calculate the YSR component matrices on the filtered data set (A, A*, A**, M, M*)
# all components are calculated on the mean data
ysr.res <- ysr.matrices(BDLmean.fil, BDLmean.time, use="pairwise.complete.obs")
# S* and R* (Pearson & Spearman correlation on individual data points)

### Hierarchical clustering

In the next step clusters are calculated on the correlation matrices using hierarchical clustering with complete linkage. Hereby, the factors are grouped into a number of clusters with the correlation within each cluster being larger than between clusters. This effectively finds groups of factors which have similar time courses. The complete linkage method defines the cluster distance between two clusters to be the maximum distance between their individual components.

The hierarchical clustering is now calculated based on the respective correlation matrices. Hierarchical clustering based on the given correlation matrix is applied with Ngroups=6 clusters. For every correlation measure the cluster plots are created. The number of clusters was choosen, so that at least >1 members exist per cluster.

```
hclust.res <- vector("list", length=length(correlation_methods))</pre>
names(hclust.res) <- correlation_methods</pre>
# Calculate the hierarical clustering: N clusters for correlation based on method
calculate_clusters <- function(cor_method, N){</pre>
  # get correlation matrix
  cor.cluster <- cor.matrices[[cor_method]]</pre>
  # perform hierarchical clustering (complete linkage & Euclidion distance measure)
  hc <- hclust(dist(cor.cluster, method="euclidian"), method="complete")</pre>
  # cut into the clusters
  groups <- cutree(hc, k=Ngroups)</pre>
  groups.hc.order <- groups[hc$order]</pre>
  # store results
  return(list(hc=hc,
              groups=groups,
              groups.hc.order=groups.hc.order))
}
Ngroups <- 6 # number of clusters
for (method in correlation_methods){
 hclust.res[[method]] <- calculate_clusters(cor_method=method, N=Ngroups)
# save clustering
save(hclust.res, file=file.path(resultsPath, "data", "hclust.res.Rdata"))
rm(method)
```

In the next step the correlation matrices are plotted in combination with the clustering results

```
# Create correlation heatmap with hierachical clustering results
correlation_heatmap_cluster <- function(method){
    # matrix and cluster results
    cor.cluster <- cor.matrices[[method]]
    hc.res <- hclust.res[[method]]
    hc <- hc.res$hc
    groups <- hc.res$groups
# colors
hmap_colors <- HeatmapColors()
colorset <- brewer.pal(Ngroups, "Set1")</pre>
```

```

#### Correlations of histological, biochemical and antibody factors

Plot correlation matrix for histological, biochemical and antibody markers. Calculation of the largest correlation between the non-transcript factors and other factors. The columns in which no correlation coefficient has abs(value) >= cor.cutoff are filtered out, i.e. only factors are retained with a absolute correlation coefficient above this threshold.

```
get_histological_correlations <- function(method="ys3", cor.cutoff=0.6){</pre>
  # correlation matrix
  cor_mat <- cor.matrices[[method]]</pre>
  # non RNA factors which were accepted by ANOVA
  hist_facs <- BDLfactors$id[anova.accept & (BDLfactors$ftype %in% c("Antibodies", "Biochemistry", "His

```

Figure 5:

#### Mean cluster time course

In the next step, we were interested in the time courses of the time course clusters: What are the typical profiles found in the different clusters and which factors are in these clusters. For the comparison of individual factors against each other and against the mean time course of the cluster the factors were normalized. The normalization was hereby performed for every factor separately based on

$$f_k^{norm}(t_{i,r}) = \frac{f_k(t_{i,r}) - \langle f_k \rangle}{max(f_x) - min(f_x)}$$

## **Decision Trees**

For the prediction of the phase/time after BDL from measured factors a decision tree was fitted on the data. The fitted decision tree model is a regression tree with the clusters as predictor variables. This allows to combine the information from multiple factors in the individual clusters, resulting in a predictive model which

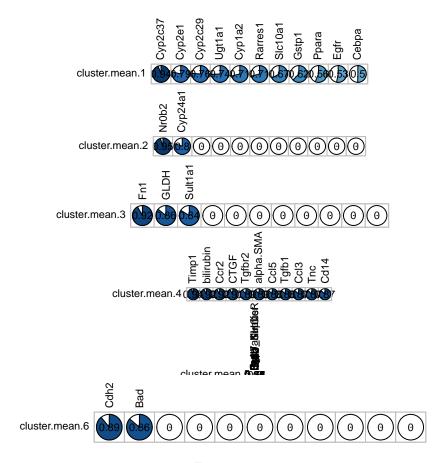

Figure 6:

is not depening on single factor variables, but uses the combined information available from multiple factors. The fitted decision tree is applicable to any subset of factors measured.

The decision tree models are fitted using the packages rpart and rpart.plot with the 6 clusters as predictor variables in the model.

In a first step the data sets are prepared for model fitting and prediction. The used data sets for model evaluation are the mean cluster data set, i.e. the mean data of all factors averaged for the clusters. The data set of all combinations of single factors from the individual clusters and a data set using 2 randomly sampled factors from every cluster.

## Regression Tree

A regression tree with the time after BDL as target variable is fitted using the cluster data as predictors. The time data is log transformed to get approximately equidistant intervals between the trainings classes. All trees are fitted with the R package rpart implementing algorithms for recursive partitioning for classification following in most details closely Breiman et. al (1984). rpart is the open-source implementation of CART.

Breiman L., Friedman J. H., Olshen R. A., and Stone, C. J. (1984) Classification and Regression Trees. Wadsworth.

The tree is built in a two-step process {Therneau2015}: First the single variable is found which best splits the data into two groups (best' will be defined later). The data is separated based on the split, and then this process is applied separately to each sub-group, and so on recursively until the subgroups either reach a minimum size (minbucket') or until no improvement can be made. The resultant model is, with a certainty, too complex, and the question arises as it does with all stepwise procedures of when to stop. The second stage of the procedure consists of using cross-validation to trim back the full tree.

An Introduction to Recursive Partitioning Using the RPART Routines TM. Therneau and E.J. Atkinson Mayo Foundation (June 29, 2015)

The splitting criterion (for classication this is either the Gini or log-likelihood function), which is used to decide which variable gives the best split for nodes in the regression trees is  $SS_T - (SS_L + SS_R)$ , with  $SS_T = \sum (y_i - \langle y \rangle)^2$  the sum of squares for the node and  $SS_R$  and  $SS_L$  the sums of squares for the left and right son. This is equivalent to choosing the split of maximize the between-groups sum-of-squares in a simple analysis of variance (see {Therneau2015}).

Two important parameters controlling the resulting tree are

- minsplit: The minimum number of observations in a node for which the routine will even try to compute a split. The default is 20 and is set to 6 in the tree calculation ( $N_r = 5$  repeats per time point).
- minbucket: The minimum number of observations in a terminal node. This defaults to minsplit/3.

```
suppressPackageStartupMessages(library(rpart))
suppressPackageStartupMessages(library(rpart.plot))
suppressPackageStartupMessages(library(caret))
dir.create(file.path(resultsPath, 'decision_tree'), showWarnings=FALSE)
```

To generate approximatly equally distant time classes for training the regression tree the log transformed time values are used. The transformation used is

$$\tilde{t_i} = log(t_i + 1)$$

```
# Transform data to log scale (for comparable time intervals)
log_transform <- function(data){</pre>
  log(data+1)
}
# Back transformation
log_transform_back <- function(log_data){</pre>
  exp(log_data)-1
# Resulting time transformations
time_transformation <- data.frame(time=BDLmean.time, log_time=log_transform(BDLmean.time))
print(round(time_transformation,2))
     time log_time

```

## Trainings data

In a first step the mean cluster trainings data for fitting the decision tree is prepared. The predictor variables are the mean samples of the clusters, the dependent variable is the log transformed time of the respective sample. The trainings set consists of the  $N_t * N_r = 40$  samples.

```

## Fit regression tree

##

Fit the log transformed time against the mean cluster data for the time points. Set control parameters for the algorithm are minsplit=6 and minbucket=2 to account for the low number of samples (N=40).

```
# formula for regression tree
formula.reg = paste("logtime \sim c1 + c2 + c3 + c4 + c5 + c6")
# fit regression tree with mean cluster data
tree.reg <- rpart(formula=formula.reg,</pre>
                  data=treedata.mean,
                  method="anova",
                  control=rpart.control(minsplit=6, minbucket=2))
# overview resulting tree
print(tree.reg)

## Prediction on trainings data

Predict data with the tree, here the time class leaves based on the mean cluster data. The regression tree predicts log classes, which are back-transformed to time in [h]. So how good is the tree performing on the trainings data set, i.e. the mean cluster data. Predictons are evaluated based on the distance between the predicted and the experimental time classes based on the following distance measure on log scale

#### TODO?

```
# L2 (euclidian) distance measurement on the log transformed data. Analog to the distance measurement i
# the regression tree.
log_distance <- function(d1, d2){
    # sums over all the distances of the samples in log space
    log_rmsd <- sqrt(sum( (log_transform(d1)-log_transform(d2) )^2 ))/length(d1)
    return(log_rmsd)
}</pre>
```

Prediction on trainings data

```
# mean cluster predictions
pred.mean.log <- predict(tree.reg, newdata=treedata.mean, type="vector")</pre>
# transformation to time in [h]
pred.mean <- log_transform_back( pred.mean.log )</pre>
# TODO: create the matrix of how is predicted (on normal and log scale)
# prediction on classification data
# BDLsamples$time
# pred.matrix.mean <- matrix(NA, nrow=nrow(node ranges), ncol=length(levels(as.factor(BDLsamples$time))
# Distance calculation (predicted to experimental)
dist.mean.all <- treedata.mean$logtime - pred.mean.log</pre>
dist.mean <- log_distance(pred.mean, BDLsamples$time)</pre>
# plot predicted ~ experimentell
plot_mean_prediction <- function(){</pre>
  par(mfrow=c(1,2))
  plot(BDLsamples$time, pred.mean, pch=15, col=rgb(0,0,1, 0.2), main="Regression Tree:\nPredicted ~ exp
       xlab="experimentell time [h]", ylab="predicted time [h]")
  abline(a=0, b=1, col=rgb(0.5,0.5,0.5,0.5))
  hist(dist.mean.all, breaks=seq(from=-1.05, to=1.05, by=0.1),
       main="Histogram prediction error:\nmean cluster data",
       col=rgb(0.5,0.5,0.5,0.5),
       xlab="logtime(exp)-logtime(pred)")
  par(mfrow=c(1,1))
}
# plot to file

# and report
plot_mean_prediction()
```

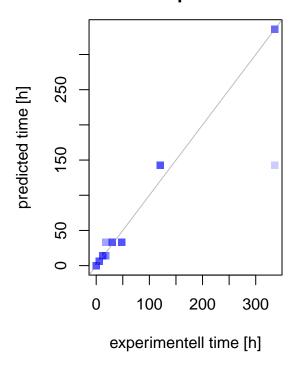

The ranges of the predicted classes by the regression trees can be calculated based on the split points on log scale. These provides the information which time points would be classified in which class in the regression tree.

```
calculate_node_ranges <- function(){
    # classes via predicted classes for cluster data
    node_levels <- levels(as.factor(pred.mean))
    # These are the predicted classes
    node_classes <- round(as.numeric(node_levels), digits=1)

# get the intervals of the time classes
    node_mean <- as.numeric(levels(as.factor(pred.mean.log)))
    node_midpoints <- (node_mean[2:length(node_mean)] + node_mean[1:(length(node_mean)-1)])/2
    # minimum of range
    node_min <- node_mean
    node_min[2:length(node_min)] <- node_midpoints
    # maximum of range
    node_max <- node_mean</pre>
```

# Regression Tree: Predicted ~ experimentell time

rm(k, tmp)
# treedata.double[[5]]
```

## Predicting test data

#### Single representative predictions

Time class prediction with regression tree for single representative from each cluster

```
print("Predicting single factor data (~ 2min) ... ")

## [1] "Predicting single factor data (~ 2min) ... "

pred.single.all <- vector("list", length(treedata.single))) for (k in (1:length(treedata.single))) {
    # prediction and back transformation
    pred.single.all[[k]] <- log_transform_back( predict(tree.reg, newdata=treedata.single[[k]], method="at") }

pred.single <- do.call("rbind", pred.single.all)

# distance for all predictions on single factor per cluster dist.single <- rep(NA, Nsingle) for (k in 1:Nsingle) {
    dist.single[k] <- log_distance(pred.single[k,], BDLsamples$time) }
}</pre>
```

## Random double representative predictions

Time class prediction with regression tree for random selection of two representatives from each clusters

```
print("Predicting double factor data (~ 1min) ... ")

## [1] "Predicting double factor data (~ 1min) ... "

pred.double.all <- vector("list", length(treedata.double)))
for (k in (1:length(treedata.double))){
    pred.double.all[[k]] <- log_transform_back( predict(tree.reg, newdata=treedata.double[[k]], method="at")}

pred.double <- do.call("rbind", pred.double.all)

# distance for predictions on 2 sampled factors per cluster
dist.double <- rep(NA, Ndouble)
for (k in 1:Ndouble){
    dist.double[k] <- log_distance(pred.double[k,], BDLsamples$time)
}</pre>
```

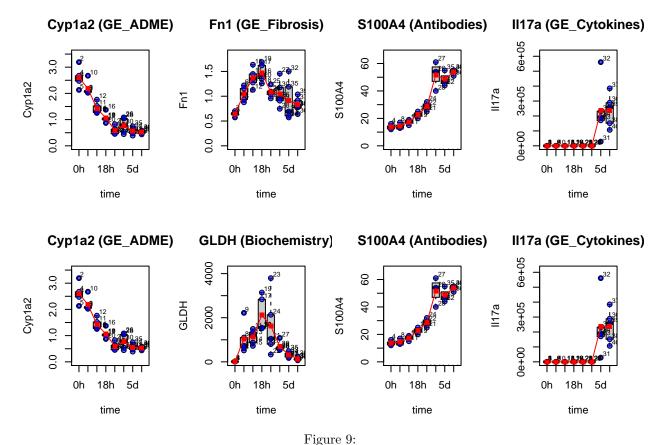

## Best factor combinations for predicting time classes

## [1] 0.05554854

Finding the best regression trees based on i) all single representatives from the clusters; and ii) single representatives only consisting of gene probes. The best is defined by minimal euclidian distance between experimental classes and predicted classes on the log scale. The best tree is not refitted with the respective factors in the tree, but the mean cluster tree uses the respective factor data for prediction.

```
# Best decision tree using all factors
# Find unique combinations with minimal distance
dist.rep.best <- min(dist.single)</pre>
# best combination of representatives for the clusters (remove duplicates)
rep.best <- unique(single.combinations[which(dist.single==dist.rep.best), c("c1", "c3", "c4", "c5")])

## Distributions of prediction distance

Plot the distance distributions of single and double representatives and the best gene and representative trees.

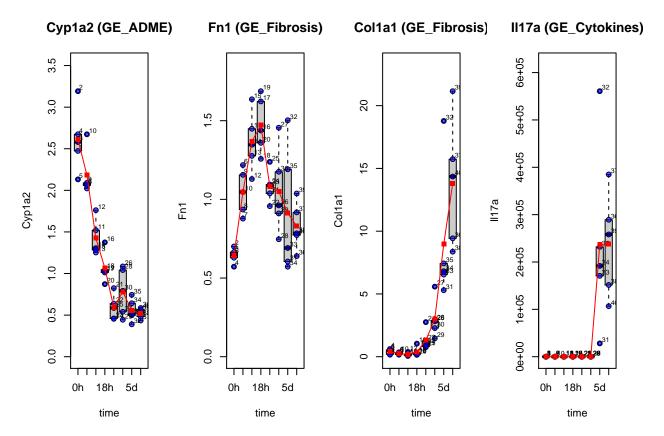

Figure 10:

```
# Plot the distributions of all the distances, i.e. log transformed predictions
# vs. the real time class
breaks <- seq(from=0, to=0.40, by=0.0125)
hist(dist.single, freq=FALSE, breaks=breaks,
    main="Distance between predicted and experimentell time",
    xlab="RMSD(time.predicted, time.exp)",
    col=rgb(0.7,0.7,0.7,1),
    ylim=c(0,15)
hist(dist.double, freq=FALSE, breaks=breaks,
     col=rgb(1,0,0, 0.5), add=TRUE)
abline(v=dist.mean, col=rgb(0,0,1, 0.5), lwd=2)
abline(v=dist.rep.best, col="black", lwd=2)
abline(v=dist.gene.best, col="grey", lwd=2)
legend("topright", legend=c("single factor", "double factor", "mean cluster"),
           col=c(rgb(0.7, 0.7, 0.7, 1),rgb(1, 0, 0, 0.5),rgb(0, 0, 1, 0.5)),
           bty="n", cex=1.0, pch=15)
```

Evaluation of the predictions. Which experimental classes were predicted in which time classes of the regression tree for the mean cluster data (trainings data), single representative from each clusters and double representatives from each cluster.

## Distance between predicted and experimentell time

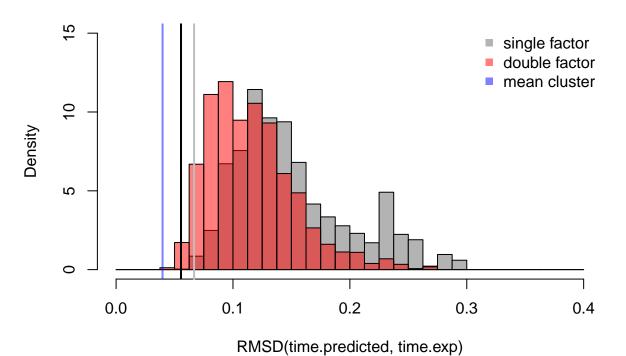

Figure 11:

```
# Predicted classes of the regression tree
node_levels <- levels(as.factor(pred.mean))
node_classes <- round(as.numeric(node_levels), digits=1)
node_classes</pre>
```

```
## [1] 0.0 6.0 14.0 33.6 142.5 336.0
```

```
